Description

Technical Field of the Invention

[0001] The present invention relates to a distance measurement sensor for an air spring based on magnetic signal triangulation which is useful for utilization in conjunction with air springs.

Background of the Invention

[0002] Height or distance measurement has a wide variety of possible applications. For instance, it is a parameter that frequently needs to be monitored to optimize the performance of various types of machinery and vehicles, such as automobiles, trucks, trains, agricultural vehicles, mining vehicles, construction vehicles, and the like. For instance, monitoring height and various distances can lead to reduced fuel consumption, improved comfort, reduced overall cost, extended product service life, and safety. In any case, the need to monitor such distance parameters generally increases with sophistication of the device and the complexity of its features.

[0003] Virtually every aspect of complex machinery may need to be tightly monitored and controlled to attain maximum advantages. For instance, constant adaptations may be required to optimize the performances and efficiency of almost every moving part of the machinery. This typically needs to be done while the operational conditions in the environment of the equipment are subject to change and can change significantly over very short time frames. Changing environmental conditions are virtually always encountered by vehicle. In addition to this vehicles frequently operate under changing conditions which can make monitoring a difficult challenge. For instance, monitoring suspension height by distance measurements between air spring components can yield useful information. However, the environment where the height measurement is being made can present a wide variety of challenges. For example, in measuring the height of a vehicle frame above the surface of a road, challenges are typically presented by road noise, dirt, dust, and vibrations which are normally present in the environment surrounding the vehicle where the measurement is being taken.

[0004] DE 10 2006 017 275 A1 and EP 1845278 A1 describe an air spring having an integrated positioning device, wherein the distance between two parts of the air spring can be measured by an analogue proximity sensor. Commonly used proximity sensors are, for example, based on an ultrasonic measurement principle which is very sensitive in noisy and vibrating environments, as the acoustic noise and the ultrasonic measurement principle are based on the same physical principle, i.e. sound propagation. These pneumatic air springs have an integrated height measuring device, a pressure chamber or an inner chamber. The exterior of the inner chamber is aligned in the analog proximity sen-

sor and a metal plate is arranged opposite to the interior of the proximity sensor. The proximity sensor and the metal plate are formed pre-adjustable to each other.

[0005] Further, DE 10 2008 064 647 A1 describes an air spring for a vehicle having a measuring device, which measuring device may transmit data and energy via pre-determined and fixed distance contactless. This pneumatic cushioning equipment has a base unit which has a pressure source and a valve unit which has an air supply made of non-metallic material, particularly plastic. A switching valve of the base unit is provided between the pressure source and appropriate valve unit of the arranged air supply.

[0006] United States Patent Publication No. 2012/0056616 A1 and EP 2 366 972 describe a sensor device for height measurement in an air spring and a corresponding method allowing determining changes in a working stroke of the air spring. These publications more specifically disclose a sensor device for a height measurement, comprising: a transceiving coil arrangement including at least one transceiving coil; a transmitting drive unit; a receiver unit; a reference coil arrangement; and a reference control unit, wherein the transceiving coil arrangement is coupled to both the transmitting drive circuit and the receiver unit, wherein the reference control unit is coupled to the reference coil arrangement, wherein the reference coil arrangement is movably positioned with respect to the transceiving coil arrangement, wherein the drive unit is adapted to drive the transceiving coil arrangement with an AC power signal of a predetermined duration for generating a magnetic field, wherein the reference control unit is adapted for accumulating energy out of the generated magnetic field and for generating a reference signal based on an amount of the accumulated energy, and wherein the receiver unit is adapted for receiving the reference signal and for outputting a signal for determining a distance between the transceiving coil arrangement and the reference coil arrangement based on at least one out of a group, the group consisting of the reference signal and the duration of the AC power signal.

[0007] US 5 521 497 A discloses an air spring comprising a distance measurement device with a magnet and a magnetic sensor, respectively mounted on a first and on a second component of the air spring, for detecting the distance between the two components.

[0008] US 2009/0128139 A1 discloses a magnet position locator for locating a magnet located underground along a road, comprising a first magnetic field sensor positioned at a first point, said first magnetic field sensor comprising a first pair of directionally disposed magnetic field sensing devices, wherein said first pair of directionally disposed magnetic field sensing devices is adapted to sense a magnetic field strength from a magnet along two differing orientations.

Summary of the Invention

[0009] It may be seen as an objective technical problem to provide a distance measuring device for an air spring with improved capabilities for supplying physical parameter measurement equipment. In particular, the physical parameter measurement equipment may be adapted for acquiring parameters like suspension height, pneumatic air pressure, and temperature.

[0010] According to the invention, a distance measuring device which can be incorporated into an air spring is provided. The distance measuring device comprises a sensing module, a target module, and an evaluating module, wherein the sensing module and the target module are mountable so as to execute a movement with respect to each other along a movement trajectory, wherein the target module comprises a magnetic field generating element having a magnetic pole axis, wherein the sensing module comprises a first magnetic field sensing array being arranged distant to the movement trajectory, the first magnetic field sensing array comprises a first magnetic field sensor and a second magnetic field sensor, wherein a main sensing direction of the first magnetic field sensor of the first magnetic field sensing array is inclined with respect to a main sensing direction of the second magnetic field sensor of the first magnetic field sensing array, so as to be capable of sensing the spatial distance to the magnetic field generating element, wherein the sensing module is connected to the evaluating module to transfer the sensed signals of the magnetic field sensors, and wherein the evaluating module is adapted to determine the spatial distance of the first magnetic field sensor and the second magnetic field sensor to the magnetic field generating element based on an orientation of the main sensing direction of the first magnetic field sensor and the main sensing direction of the second magnetic field sensor, and the sensed signal of the first magnetic field sensor and the second magnetic field sensor, wherein the main sensing direction of the first magnetic field sensor of the first magnetic field sensing array is substantially orthogonal to the main sensing direction of the second magnetic field sensor of the first magnetic field sensing array, wherein the main sensing direction of the first magnetic field sensor of the first magnetic field sensing array is substantially parallel to the movement trajectory and the main sensing direction of the second magnetic field sensor of the first magnetic field sensing array is substantially orthogonal to the movement trajectory.

[0011] The movement trajectory may be a line which corresponds to the line of movement of the sensing module and the target module with respect to each other. In other words, there is a lateral offset between the movement trajectory and the first magnetic field sensing array.

[0012] The inclination of the main sensing directions of the first and second magnetic field sensors with respect to each other means that a central axis of the first magnetic field sensor is inclined with respect to the central

axis of the second magnetic field sensor.

[0013] In one specific embodiment of this invention the magnetic field generating element of the target module comprises a permanent magnet having the magnetic pole axis.

[0014] In other words, the permanent magnet of the target module is a passive component which may have a high reliability and a low risk of failure.

[0015] In another specific embodiment of this invention the magnetic pole axis is aligned to the movement trajectory.

[0016] This arrangement may increase the sensitivity of the distance measuring device and may provide measurement results with increased accuracy.

[0017] The arrangement of the invention enables a differential mode sensing of the magnetic field and therefore the compensation of the effects of unwanted magnetic stray fields.

[0018] In still another embodiment of this invention the sensing module comprises a second magnetic field sensing array to provide in combination with the first magnetic field sensing array a differential mode sensor, wherein the second magnetic field sensing array has a predetermined distance to the first magnetic field sensing array.

[0019] The second magnetic field sensing array and the first magnetic field sensing array are located spaced apart from each other. Therefore, any one of these array may detect the magnetic field strength at its position. As the relative positions of the first and second magnetic field sensing arrays with respect to each other are known, a more accurate measurement can be carried out since the relative strength of the magnetic field at the positions of the first and second magnetic field sensing arrays is taken as a basis for distance measurement.

[0020] In a further specific embodiment of this invention the first magnetic field sensing array, the second magnetic field sensing array and the magnetic field generating element form a substantially rectangular triangle, with the second magnetic field sensing array at the rectangle and on the movement trajectory.

[0021] The first and second magnetic field sensing arrays are arranged at the same height with respect to the movement trajectory, or, in other words, a connection line between the first and second magnetic field sensing arrays is perpendicular to the movement trajectory.

[0022] In a further embodiment of this invention the second magnetic field sensing array comprises a first magnetic field sensor and a second magnetic field sensor, wherein the main sensing direction of the first magnetic field sensor of the second magnetic field sensing array is inclined with respect to the main sensing direction of the second magnetic field sensor of the second magnetic field sensing array. In another embodiment of the subject invention the main sensing direction of the first magnetic field sensor of the second magnetic field sensing array is substantially orthogonal to the main sensing direction of the second magnetic field sensor of the second magnetic field sensing array.

[0023] In still another embodiment of this invention the main sensing direction of the first magnetic field sensor of the second magnetic field sensing array is substantially orthogonal to the main sensing direction of the second magnetic field sensor of the second magnetic field sensing array, wherein the main sensing direction of the first magnetic field sensor of the second magnetic field sensing array is substantially parallel to the movement trajectory and the main sensing direction of the second magnetic field sensor of the second magnetic field sensing array is substantially orthogonal to the movement trajectory. In a further embodiment of this invention the movement trajectory is a substantially straight line, so that a magnetic pole axis of the magnetic field generating element is oriented towards the first magnetic field sensing array.

[0024] The subject invention further reveals an air spring comprising: a first mounting plate being adapted to be mounted to a chassis of a vehicle, a second mounting plate being adapted to be mounted to a wheel suspension, and a distance measuring device as described above and hereinafter, and wherein the sensing module is mounted to the first mounting plate, and wherein the target module is mounted to the second mounting plate.

[0025] The subject invention also reveals an air spring comprising a piston, a top plate, a flexible member, and a distance sensor, wherein the flexible member is affixed to the piston and the top plate, wherein the piston, the top plate and the flexible member define a pressurizable chamber, wherein the distance sensor is a distance measuring device as described above and hereinafter, wherein the sensing module and the target module are situated within the pressurizable chamber.

[0026] This invention offers an array of benefits. For instance, wiring connections can be arranged only at one end of the air-spring (such as from and to the base point, for example). Also, there is no need to provide electric power or any other wiring to the target point which is placed opposite to the base point. The target-point is a passive component which offers high reliability and a low risk of failure. The Magnetic Field Sensor (MFS) array is relatively small and fits easily inside the rubber belly of the air-spring. Optionally, the MFS array can be placed outside of the flexible member (belly) of the air-spring.

[0027] There is no need to breach the air-tight enclosure of the flexible member (rubber belly) for the sensor system to function. Low design complexity and low cost design can be achieved with the air springs of this invention. Any type of directionally sensitive Magnetic Field Sensing (MFS) devices can be used, as long as they can differentiate between positive and negative magnetic field strength. This includes but is not limited to: inductors (requires flux gate electronics, Hall-effect, MR, and GMR).

[0028] Virtually any desired measurement signal bandwidth can be achieved as this sensing technology is measuring a static magnetic field source (is not relying on an alternating magnetic field source signal). Therefore the sensing technology of this invention is very fast re-

sponding when trying to measure not only the absolute position of the target-point in relation to the base-point, but also trying to determine and quantify potential Air-Spring vibrations. In the practice of this invention the applied magnetic field sensor (MFS) array may cancel the unwanted effects caused by uniform magnetic stray fields. This sensor solution may also be insensitive to the magnetic field of the Earth.

[0029] These and other aspects of the present invention will become apparent from and elucidated with reference to the embodiments described hereinafter.

Brief Description of the Drawings

[0030]

Fig. 1 illustrates a non-contact distance sensor system in accordance with this invention.

Fig. 2 illustrates the manner in which the sensor system of this invention functions via a dual axes magnetic field sensor array and a target point or magnetic field signal source.

Fig. 3 illustrates the relationship between the movement axis "a" and the horizontal axis "b" in a distance sensor system in accordance with this invention.

Fig. 4 illustrates how the vector values "a2" and "b2" relate to the signal measurements taken from the MFS sensor array in a distance sensor system in accordance with one embodiment of this invention.

Fig. 5 illustrates the relationship between the angle α and the angle β which can be used to calculate the distance a in accordance with one embodiment of this invention.

Fig. 6 illustrates sensor electronics that can be employed in conjunction with a distance sensor system of one embodiment of this invention.

Detailed Description of the Invention

[0031] For purposes hereof it should be understood that in referring to distances between two points the points are a base point (from where the measurement will start) and the target point to which the distance is measured. When aiming for a non-contact distance measurement solution, and when placing the distance sensing system at the base point, then the used measurement system has to be able to physically "detect", "feel", or "sense" the target point, in some way. There may be a multitude of fundamental different ways to accomplish this purpose. Some of these solutions can be optically based (such as visible light, and invisible light), sound based (for instance, audible and non-audible sounds) or physical based measurements. The measurement solution which is best suited for a specific application may depend on many factors, including: environmental conditions (interfering lights, interfering sound, changing ambient pressure, temperature, dust, and humidity), space availability for the measurement

system, the targeted measurement range (millimeters, meters, kilometers), required measurement resolution and absolute accuracy, cost limitations, and the like.

[0032] The herein described distance measurement solution is specifically directed to pneumatic powered, air-spring applications. It is applicable to the air springs which are employed in a wide variety of applications including, but not limited to machinery and vehicles, such as automobiles, trucks, trains, agricultural vehicles, mining vehicles, construction vehicles, and the like.

[0033] The air-spring design to which this invention is applicable includes a flexible member (an elastic rubber belly) that is mounted in an air-tight manner onto top and bottom plates to define an air tight (pressurizable) chamber. By pumping pressured air into the pressurizable chamber the air-spring will expand and by releasing the air from the pressurizable chamber the air-spring will begin to collapse. Usually mechanically controlled or electrically controlled pneumatic valves are used to change the amount of air within the pressurizable chamber of the air spring.

[0034] The total maximum distance that needs to be measured is equivalent to the working stroke range of the air-spring. The total working stroke of an air-spring is the difference in distance between when the air-spring is fully expanded (the maximal working length of the air-spring) and when the air-spring is fully contracted (the shortest possible working length of the air-spring). In other words, this working stroke is the changes in length of the air-spring when fully pumped-up (maximum practical air-volume within the air-spring belly) and when almost all of the air inside the air-spring has been pumped-out (lowest practical air-volume within the air-spring belly). The term "air" as used in this context includes any gas or mixtures of gasses which is inert to the air spring and includes air, nitrogen, helium, other Noble gases, nitrogen enhanced air and helium enhanced air, for example. In particular, the term "air" when referring to an air spring may be understood as a synonym for any compressible gas.

[0035] For purposes hereof the targeted distance measurement is typically within the range of a few millimeters to around 400 millimeters. The targeted measurement resolution and measurement repeatability is typically within the range of about 1 mm to 5 mm. The fundamental design characteristics of a standard air-spring may make it difficult or near impossible to apply typical distance measurement solutions. For instance, due to the fact that the flexible member (rubber belly) forms the pressurizable chamber. It may also be very inconvenient and may increase costs in scenarios where air-tight passages need to be tooled into the top or bottom plate of the air spring to accommodate electric cables for electric power supply or other purposes. Additionally air-tight connectors of any type are expensive and will typically have an adverse effect on the reliability of the air-springs utilizing such technology.

[0036] The air-pressure inside the air-spring belly con-

stantly changes during normal usage. As the air pressure changes the quality and composition of the air is also subject to continual change. Such changes in for instance the level of humidity and contaminants (dust in the air) can dramatically affect sound based measurement systems. Humidity and dust will also have a negative effect when using light based sensing technologies.

[0037] The sensing solution of this invention will operate on magnetic principles as they are not affected by light, sound, air-pressure, dust, and/or humidity. In addition, magnetic field based sensor systems can easily penetrate the rubber belly of an air spring, which allows for the magnetic based sensor system to be mounted outside of the rubber belly of the air spring.

[0038] The sensor system of this invention may be described as consisting three main parts: (1) the sensing module (or Magnetic Field Sensor Array), the sensor electronics, and the target-point. The sensing module and the sensing electronics are connected with each other by a number of insulated electrical wires (for example 4 wires can be utilized. The sensing module can be placed at the one end of the air-spring and can be referred to as the base-point. The sensor electronics can be powered by a low DC (direct current) voltage. The target-point is typically a small and high strength permanent magnet. The physical dimension and the absolute surface-magnetic-field-strengths of the permanent magnet are subject to a number of application dictated parameters, including the measurement distance to be covered, available space, and environmental factors, including ferro-magnetic objects that may be situated near to the measurement path. For purposes hereof the "measurement path" is a vertical straight line between the target-point and the base point. In general, larger more powerful permanent magnets are needed with larger measurement distances with stronger surface-magnetic-field-strengths being required. In any case, the area around the measurement should be free of moving ferro-magnetic objects as they can interfere negatively with the distance measurement to be taken. However, within limits, static (not moving) ferro-magnetic objects can be tolerated with appropriate correction factors.

[0039] Figure 1 illustrates an exemplary embodiment of the Non-Contact Distance Sensor system (sensing module and Target-Point only. Not shown is the sensor electronics and the wiring to the electronics.). A permanent magnet (Target-Point 3) is moving up and down the "movement axis", whereby the magnetic pole-axis of the permanent magnet has to be aligned with the movement axis. The movement axis is a straight line and goes through the Base-Point, where the Magnetic Field Sensor (MFS) array 2 is placed. The distance "b" between the two MFS sensing arrays (MFS 1 and MFS 2) is a fixed value and cannot be changed in a given application. The distance "b" and the magnetic field strength of the permanent magnet (Target Point 3) defines the maximal possible measurement range or "distance" "a".

[0040] When flipping around the magnetic pole axis of

the permanent magnet by 90 degree (for example), then the possible absolute measurement range "a" will be greatly reduced. At the same time the sensitivity towards ferro-magnetic objects that are placed nearby will significantly increase.

[0041] The two MFS arrays are required to build a differential mode sensors in order to compensate for the unwanted effects of uniform magnetic stray fields. If and when potential uniform magnetic stray fields can be ignored, then only the MFS 1 is required for accurate distance measurements.

[0042] One of the most important features of the here described distance sensor system may be, that the distance measurement is not relying on the absolute magnetic field strength of the Target-Point (Permanent Magnet). For example, this means that this sensor solution can compensate for the effects of aging of the permanent magnet, or changes of the operating temperatures.

[0043] To explain how this sensor system functions, the placements of the individual sensing module components are re-named and described in more detail in Figure 2. It is assumed that the MFS (Magnetic Field Sensor) array is built by using inductor based sensors. However, any other type of directional sensitive MFS device can be used as well as long as such sensors can distinguish between positive and negative magnetic fields and are capable of directional magnetic field measurements. The most important of the two shown MFS arrays is the one at the right, built from two inductors, called L3 (horizontally placed) and L2 (vertically placed).

[0044] When using inductors to measure the magnetic field strength of a permanent magnet (static magnetic field source) then the inductor has to be connected to a flux-gate-type electronic circuit. The output of the flux-gate electronic circuit is a voltage that is equivalent and direct proportionate to the detected and measured magnetic field strength. When using Hall-effect sensors (for example) then there is no need for a flux-gate electronic circuit as most Hall-effect sensors provide an analogue signal output. The Voltage value of the Hall-effect sensor output is direct proportionate to the measured magnetic field strength.

[0045] As illustrated in Figure 3, the distance between the two MFS arrays (MFS 1 and MFS 2) is herein defined as "b", while the distance between the MFS array at the left and the Target-Point (permanent magnet) is called "a". In Figure 3, the angle between the movement axis "a" (which is a straight line between the target-point and the MFS array at the left) and the horizontal axis "b" (the distance between MFS1 and MFS2) is 90°. This angle is identified in Figure 3 as γ .

[0046] Taking the two values VL2 and VL3, it is possible to calculate the absolute Vector value ("c") caused by the permanent magnet, and the absolute angle this vector is pointing towards. Depending on the applied algorithm, either the angle α or the angle β can be calculated. In the following the algorithm is shown to calculate the angle β . The measurement value of VL2 will change

approximately in the same way as the vertical Vector signal portion "a₂" is changing and the measurement value VL3 is changing in the same rate as the horizontal Vector signal portion "b₂". It should be noted as illustrated in Figure 4 that the vector values "a₂" and "b₂" belong to the signal measurements taken from the right MFS Sensor Array (MFS 1). The Vector values "a" and "b" are the distance measurements and distance calculations attained with the sensor system of this invention.

[0047] When taking the two values of the signal amplitudes that are indirectly generated by the MFS L3 (here called VL3) and by the MFS L2 (here called VL2) and applying the algorithm:

$$\beta = \arctan (V_{L3}/V_{L2})$$

$$VL3 \sim b_2$$

$$VL2 \sim a_2$$

$$\beta = \arctan (b_2/a_2)$$

[0048] The result of this algorithm is the angle β . The distance "a" which is the distance between the target point (a permanent magnet) and the base point changes with the changes in angle β and can be calculated utilizing the algorithm provided above. On advantage of this algorithm may be that any change of the absolute magnetic signal strength of the used permanent magnet is almost of no consequence. The angle " α " and " β " will remain the same, even if the magnetic signal strength of the permanent is increasing or decreasing by a certain amount within certain reasonable limits.

[0049] As illustrated in Figure 5, when knowing the angle " α " or " β ", then it is easy to calculate the absolute distance "a" by applying the algorithm (Note: the distance "b" is a fixed value and is known):

$$a = b \cot(\arctan (b_2/a_2))$$

[0050] In order to compensate for the unwanted effects of uniform magnetic stray fields (like the Earth Magnetic Field), additional magnetic field sensing devices are used to allow building two sets of "differential mode" MFS arrays. The inductors L0 and L3 will form the first differential mode magnetic field sensor (V L Horizontal = L3 - L0), and inductors L1 and L2 will form the second differential mode magnetic field sensor (V L Vertical = L2 - L1). As before, the two values VL Horizontal and VL Vertical are now used to calculate the angle " β ". In this case, this angle value may not be affected by uniform magnetic stray fields.

[0051] Figure 6 is an illustration of an example of sen-

sensor electronics. To execute different type of algorithms, and to keep the flexibility of making changes to the algorithms, it may be advisable to use a micro controller in the sensor electronics. However, this may be optional. Figure 6 illustrates two channel sensor electronics and how the individual magnetic field sensing devices are connected in series with each other. When using Hall-effect sensors then the output voltages of two Hall-effect sensors have to be subtracted from each other using an appropriate analogue circuitry. Alternatively, the four voltages generated by the four Hall-effect sensors used can be fed directly into the Micro Controller where the subtraction activity will be executed.

[0052] It should be understood that the features described in individual exemplary embodiments may also be combined with each other in order to obtain a more fail safe air spring height sensor or air spring as well as to enable error detection and correction of the measured height signal. While certain representative embodiments and details have been shown for the purpose of illustrating the subject invention, it will be apparent to those skilled in this art that various changes and modifications can be made therein without departing from the scope of the appended claims.

Claims

1. Air spring distance measuring device comprising: a sensing module (1), a target module (3), and an evaluating module, wherein the sensing module and the target module are mountable so as to execute a movement with respect to each other along a movement trajectory, wherein the target module (3) comprises a magnetic field generating element having a magnetic pole axis, wherein the sensing module comprises a first magnetic field sensing array (MFS1) being arranged distant to the movement trajectory, the first magnetic field sensing array comprises a first magnetic field sensor (L2) and a second magnetic field sensor (L3), wherein a main sensing direction of the first magnetic field sensor (L2) of the first magnetic field sensing array (MFS1) is inclined with respect to a main sensing direction of the second magnetic field sensor (L3) of the first magnetic field sensing array (MFS1), so as to be capable of sensing the spatial distance to the magnetic field generating element, wherein the sensing module is connected to the evaluating module to transfer the sensed signals of the magnetic field sensors, and wherein the evaluating module is adapted to determine the spatial distance of the first magnetic field sensor (L2) and the second magnetic field sensor (L3) to the magnetic field generating element based on an orientation of the main sensing direction of the first magnetic field sensor and the main sensing direction of the second magnetic field sensor, and the sensed signal of the first magnetic field sensor and the second magnetic field sensor
2. Air spring distance measuring device according to claim 1, wherein the magnetic field generating element of the target module (3) comprises a permanent magnet having the magnetic pole axis.
3. Air spring distance measuring device according to claim 1 or 2 wherein the magnetic pole axis being aligned to the movement trajectory.
4. Air spring distance measuring device according to any one of the preceding claims wherein the sensing module comprises a second magnetic field sensing array (MFS2) to provide in combination with the first magnetic field sensing array (MFS1) a differential mode sensor, wherein the second magnetic field sensing array has a predetermined distance (b) to the first magnetic field sensing array.
5. Air spring distance measuring device according to claim 4 wherein the first magnetic field sensing array (MFS1), the second magnetic field sensing array (MFS2) and the magnetic field generating element (3) form a substantially rectangular triangle, with the second magnetic field sensing array at the rectangle and on the movement trajectory.
6. Air spring distance measuring device according to any one of claims 4 and 5 wherein the second magnetic field sensing array (MFS2) comprises a first magnetic field sensor (L1) and a second magnetic field sensor (L0), wherein the main sensing direction of the first magnetic field sensor (L1) of the second magnetic field sensing array (MFS2) is inclined with respect to the main sensing direction of the second magnetic field sensor (L0) of the second magnetic field sensing array (MFS2).
7. Air spring distance measuring device according to any one of claims 4 to 6 wherein the main sensing direction of the first magnetic field sensor (L1) of the second magnetic field sensing array (MFS2) is substantially orthogonal to the main sensing direction of the second magnetic field sensor (L0) of the second magnetic field sensing array.

8. Air spring distance measuring device according to any one of claims 4 to 7 wherein the main sensing direction of the first magnetic field sensor (L1) of the second magnetic field sensing array (MFS2) is substantially orthogonal to the main sensing direction of the second magnetic field sensor (L0) of the second magnetic field sensing array (MFS2), wherein the main sensing direction of the first magnetic field sensor (L1) of the second magnetic field sensing array (MFS2) is substantially parallel to the movement trajectory and the main sensing direction of the second magnetic field sensor (L0) of the second magnetic field sensing array (MFS2) is substantially orthogonal to the movement trajectory.
9. Air spring distance measuring device according to any one of the preceding claims wherein the movement trajectory is a substantially straight line, so that a magnetic pole axis of the magnetic field generating element is oriented towards the first magnetic field sensing array.
10. An air spring comprising: a first mounting plate being adapted to be mounted to a chassis of a vehicle, a second mounting plate being adapted to be mounted to a wheel suspension, and an air spring distance measuring device according to any one of the preceding claims, wherein the sensing module (1, 2) is mounted to the first mounting plate, and wherein the target module (3) is mounted to the second mounting plate.
11. Air spring according to claim 10 which further comprises a flexible member, wherein the first mounting plate, the second mounting plate, and the flexible member define a pressurizable chamber, and wherein the sensing module and the target module are situated within the pressurizable chamber.

Patentansprüche

1. Luftfeder-Distanzmessvorrichtung, umfassend: ein Erfassungsmodul (1), ein Zielmodul (3) und ein Auswertungsmodul, wobei das Erfassungsmodul und das Zielmodul montierbar sind, um eine Bewegung in Bezug aufeinander entlang einer Bewegungsbahn auszuführen, wobei das Zielmodul (3) ein Magnetfeld-Erzeugungselement mit einer Magnetpolachse umfasst, wobei das Erfassungsmodul eine erste Magnetfeld-Erfassungsanordnung (MFS1) umfasst, die entfernt zu der Bewegungsbahn angeordnet ist, die erste Magnetfeld-Erfassungsanordnung einen ersten Magnetfeldsensor (L2) und einen zweiten Magnetfeldsensor (L3) umfasst, wobei eine Haupterfassungsrichtung des ersten Magnetfeldsensors (L2) der ersten Magnetfeld-Erfassungsanordnung (MFS1) in Bezug auf eine Haupterfassungsrichtung

des zweiten Magnetfeldsensors (L3) der ersten Magnetfeld-Erfassungsanordnung (MFS1) geneigt ist, um imstande zu sein, die räumliche Distanz zu dem Magnetfeld-Erzeugungselement zu erfassen, wobei das Erfassungsmodul mit dem Auswertungsmodul verbunden ist, um die erfassten Signale der Magnetfeldsensoren zu übertragen, und wobei das Auswertungsmodul angepasst ist zum Bestimmen der räumlichen Distanz des ersten Magnetfeldsensors (L2) und des zweiten Magnetfeldsensors (L3) zu dem Magnetfeld-Erzeugungselement basierend auf einer Ausrichtung der Haupterfassungsrichtung des ersten Magnetfeldsensors und der Haupterfassungsrichtung des zweiten Magnetfeldsensors und dem erfassten Signal des ersten Magnetfeldsensors und des zweiten Magnetfeldsensors, wobei die Haupterfassungsrichtung des ersten Magnetfeldsensors (L2) der ersten Magnetfeld-Erfassungsanordnung (MFS1) im Wesentlichen orthogonal zu der Haupterfassungsrichtung des zweiten Magnetfeldsensors (L3) der ersten Magnetfeld-Erfassungsanordnung (MFS1) ist, wobei die Haupterfassungsrichtung des ersten Magnetfeldsensors (L2) der ersten Magnetfeld-Erfassungsanordnung (MFS1) im Wesentlichen parallel zu der Bewegungsbahn ist und die Haupterfassungsrichtung des zweiten Magnetfeldsensors (L3) der ersten Magnetfeld-Erfassungsanordnung (MFS1) im Wesentlichen orthogonal zu der Bewegungsbahn ist.

2. Luftfeder-Distanzmessvorrichtung nach Anspruch 1, wobei das Magnetfeld-Erzeugungselement des Zielmoduls (3) einen Dauermagneten, der die Magnetpolachse aufweist, umfasst.
3. Luftfeder-Distanzmessvorrichtung nach Anspruch 1 oder 2, wobei die Magnetpolachse mit der Bewegungsbahn ausgerichtet ist.
4. Luftfeder-Distanzmessvorrichtung nach einem der vorhergehenden Ansprüche, wobei das Erfassungsmodul eine zweite Magnetfeld-Erfassungsanordnung (MFS2) umfasst, um in Kombination mit der ersten Magnetfeld-Erfassungsanordnung (MFS1) einen Differenzialmodensensor bereitzustellen, wobei die zweite Magnetfeld-Erfassungsanordnung eine im Voraus bestimmte Distanz (b) zu der ersten Magnetfeld-Erfassungsanordnung aufweist.
5. Luftfeder-Distanzmessvorrichtung nach Anspruch 4, wobei die erste Magnetfeld-Erfassungsanordnung (MFS1), die zweite Magnetfeld-Erfassungsanordnung (MFS2) und das Magnetfeld-Erzeugungselement (3) ein im Wesentlichen rechtwinkliges Dreieck mit der zweiten Magnetfeld-Erfassungsanordnung auf dem rechten Winkel und auf der Bewegungsbahn bilden.

6. Luftfeder-Distanzmessvorrichtung nach einem der Ansprüche 4 und 5, wobei die zweite Magnetfeld-Erfassungsanordnung (MFS2) einen ersten Magnetfeldsensor (L1) und einen zweiten Magnetfeldsensor (L0) umfasst, wobei die Haupterfassungsrichtung des ersten Magnetfeldsensors (L1) der zweiten Magnetfeld-Erfassungsanordnung (MFS2) in Bezug auf die Haupterfassungsrichtung des zweiten Magnetfeldsensors (L0) der zweiten Magnetfeld-Erfassungsanordnung (MFS2) geneigt ist.
7. Luftfeder-Distanzmessvorrichtung nach einem der Ansprüche 4 bis 6, wobei die Haupterfassungsrichtung des ersten Magnetfeldsensors (L1) der zweiten Magnetfeld-Erfassungsanordnung (MFS2) im Wesentlichen orthogonal zu der Haupterfassungsrichtung des zweiten Magnetfeldsensors (L0) der zweiten Magnetfeld-Erfassungsanordnung ist.
8. Luftfeder-Distanzmessvorrichtung nach einem der Ansprüche 4 bis 7, wobei die Haupterfassungsrichtung des ersten Magnetfeldsensors (L1) der zweiten Magnetfeld-Erfassungsanordnung (MFS2) im Wesentlichen orthogonal zu der Haupterfassungsrichtung des zweiten Magnetfeldsensors (L0) der zweiten Magnetfeld-Erfassungsanordnung (MFS2) ist, wobei die Haupterfassungsrichtung des ersten Magnetfeldsensors (L1) der zweiten Magnetfeld-Erfassungsanordnung (MFS2) im Wesentlichen parallel zu der Bewegungsbahn ist und die Haupterfassungsrichtung des zweiten Magnetfeldsensors (L0) der zweiten Magnetfeld-Erfassungsanordnung (MFS2) im Wesentlichen orthogonal zu der Bewegungsbahn ist.
9. Luftfeder-Distanzmessvorrichtung nach einem der vorhergehenden Ansprüche, wobei die Bewegungsbahn eine im Wesentlichen gerade Linie ist, so dass eine Magnetpolachse des Magnetfeld-Erzeugungselement hin zu der ersten Magnetfeld-Erfassungsanordnung ausgerichtet ist.
10. Luftfeder, umfassend: eine erste Montagsplatte, die angepasst ist, an ein Chassis eines Fahrzeugs montiert zu werden, eine zweite Montagsplatte, die angepasst ist, an eine Radaufhängung montiert zu werden, und eine Luftfeder-Distanzmessvorrichtung nach einem der vorhergehenden Ansprüche, wobei das Erfassungsmodul (1, 2) an die erste Montagsplatte montiert ist und wobei das Zielmodul (3) an die zweite Montagsplatte montiert ist.
11. Luftfeder nach Anspruch 10, die ferner ein flexibles Glied umfasst, wobei die erste Montagsplatte, die zweite Montagsplatte und das flexible Glied eine druckbeaufschlagbare Kammer definieren und wobei das Erfassungsmodul und das Zielmodul im In-

tern der druckbeaufschlagbaren Kammer angeordnet sind.

5 Revendications

1. Dispositif de mesure de distance à ressort pneumatique comprenant : un module de détection (1), un module cible (3) et un module d'évaluation, le module de détection et le module cible pouvant être montés de manière à exécuter un mouvement l'un par rapport à l'autre le long d'une trajectoire de mouvement, le module cible (3) comprenant un élément générateur de champ magnétique ayant un axe de pôle magnétique, le module de détection comprenant un premier réseau de détection de champ magnétique (MFS1) qui est agencé à distance de la trajectoire de mouvement, le premier réseau de détection de champ magnétique comprenant un premier capteur de champ magnétique (L2) et un second capteur de champ magnétique (L3), une direction de détection principale du premier capteur de champ magnétique (L2) du premier réseau de détection de champ magnétique (MFS1) étant inclinée par rapport à une direction de détection principale du second capteur de champ magnétique (L3) du premier réseau de détection de champ magnétique (MFS1), de manière à pouvoir détecter la distance spatiale par rapport à l'élément générateur de champ magnétique, le module de détection étant relié au module d'évaluation pour transférer les signaux détectés des capteurs de champ magnétique, et le module d'évaluation étant adapté pour déterminer la distance spatiale du premier capteur de champ magnétique (L2) et du second capteur de champ magnétique (L3) par rapport à l'élément générateur de champ magnétique sur la base d'une orientation de la direction de détection principale du premier capteur de champ magnétique et de la direction de détection principale du second capteur de champ magnétique, et du signal détecté du premier capteur de champ magnétique et du second capteur de champ magnétique
- la direction de détection principale du premier capteur de champ magnétique (L2) du premier réseau de détection de champ magnétique (MFS1) étant sensiblement orthogonale à la direction de détection principale du second capteur de champ magnétique (L3) du premier réseau de détection de champ magnétique (MFS1), la direction de détection principale du premier capteur de champ magnétique (L2) du premier réseau de détection de champ magnétique (MFS1) étant sensiblement parallèle à la trajectoire de mouvement, et la direction de détection principale du second capteur de champ magnétique (L3) du premier réseau de détection de champ magnétique (MFS1) étant sensiblement orthogonale à la trajectoire de mouvement.

2. Dispositif de mesure de distance à ressort pneumatique selon la revendication 1, l'élément générateur de champ magnétique du module cible (3) comprenant un aimant permanent ayant l'axe de pôle magnétique. 5
3. Dispositif de mesure de distance à ressort pneumatique selon la revendication 1 ou 2, l'axe de pôle magnétique étant aligné sur la trajectoire de mouvement. 10
4. Dispositif de mesure de distance à ressort pneumatique selon l'une quelconque des revendications précédentes, le module de détection comprenant un second réseau de détection de champ magnétique (MFS2) pour fournir en combinaison avec le premier réseau de détection de champ magnétique (MFS1) un capteur à mode différentiel, le second réseau de détection de champ magnétique ayant une distance prédéterminée (b) par rapport au premier réseau de détection de champ magnétique. 15
5. Dispositif de mesure de distance à ressort pneumatique selon la revendication 4, le premier réseau de détection de champ magnétique (MFS1), le second réseau de détection de champ magnétique (MFS2) et l'élément générateur de champ magnétique (3) formant un triangle sensiblement rectangle, avec le second réseau de détection de champ magnétique au niveau de l'angle droit et sur la trajectoire de mouvement. 20
6. Dispositif de mesure de distance à ressort pneumatique selon l'une quelconque des revendications 4 et 5, le second réseau de détection de champ magnétique (MFS2) comprenant un premier capteur de champ magnétique (L1) et un second capteur de champ magnétique (L0), la direction de détection principale du premier capteur de champ magnétique (L1) du second réseau de détection de champ magnétique (MFS2) étant inclinée par rapport à la direction de détection principale du second capteur de champ magnétique (L0) du second réseau de détection de champ magnétique (MFS2). 25
7. Dispositif de mesure de distance à ressort pneumatique selon l'une quelconque des revendications 4 à 6, la direction de détection principale du premier capteur de champ magnétique (L1) du second réseau de détection de champ magnétique (MFS2) étant sensiblement orthogonale à la direction de détection principale du second capteur de champ magnétique (L0) du second réseau de détection de champ magnétique. 30
8. Dispositif de mesure de distance à ressort pneumatique selon l'une quelconque des revendications 4 à 7, la direction de détection principale du premier cap- 35
- teur de champ magnétique (L1) du second réseau de détection de champ magnétique (MFS2) étant sensiblement orthogonale à la direction de détection principale du second capteur de champ magnétique (L0) du second réseau de détection de champ magnétique (MFS2), la direction de détection principale du premier capteur de champ magnétique (L1) du second réseau de détection de champ magnétique (MFS2) étant sensiblement parallèle à la trajectoire de mouvement, et la direction de détection principale du second capteur de champ magnétique (L0) du second réseau de détection de champ magnétique (MFS2) étant sensiblement orthogonale à la trajectoire de mouvement. 40
9. Dispositif de mesure de distance à ressort pneumatique selon l'une quelconque des revendications précédentes, la trajectoire de mouvement étant une ligne sensiblement droite, de sorte qu'un axe de pôle magnétique de l'élément générateur de champ magnétique est orienté vers le premier réseau de détection de champ magnétique. 45
10. Ressort pneumatique comprenant : une première plaque de montage adaptée pour être montée sur un châssis d'un véhicule, une seconde plaque de montage adaptée pour être montée sur une suspension de roue, et un dispositif de mesure de distance à ressort pneumatique selon l'une quelconque des revendications précédentes, le module de détection (1, 2) étant monté sur la première plaque de montage, et le module cible (3) étant monté sur la seconde plaque de montage. 50
11. Ressort pneumatique selon la revendication 10, qui comprend en outre un élément flexible, la première plaque de montage, la seconde plaque de montage et l'élément flexible définissant une chambre pouvant être mise sous pression, et le module de détection et le module cible étant situés à l'intérieur de la chambre pouvant être mise sous pression. 55
